

AS-IS and TO-BE Process Flows

AI-Powered CMO Response Time Reduction & Incident Management Automation System | Sanitized portfolio case study

1. Purpose

This document shows how the automation initiative transforms the operational flow from manual, fragmented incident handling to a standardized process with intelligent alert processing, automatic follow-up, escalation and dashboard visibility.

2. AS-IS Process: Manual Incident Management

2.1 Reactive Incident Handling

Manual intervention is required at every handoff, delaying visibility and making follow-up dependent on individual availability.

2.2 Proactive Critical Incident Monitoring

Critical incidents are identified through periodic review rather than a near real-time, systematic monitoring view.

3. AS-IS Pain Points

- Critical incidents can take approximately 10 to 45 minutes to reach the appropriate response team.
- Ownership, reminder timing and escalation are inconsistent.
- Manual monitoring and reporting consume operational capacity.
- Leadership does not have near real-time, consolidated visibility of open incidents and performance.

4. TO-BE Process: AI-Powered Incident Management

4.1 Reactive Incident Automation

The automation standardizes the route from eligible incoming incident to ownership, follow-up, escalation and closure.

4.2 Proactive Incident Monitoring

Critical open incidents are aggregated into an actionable, area-wise management view.

5. Expected Process Outcomes

Before Automation	After Automation
Manual monitoring and alert interpretation	Rules-based alert processing and structured notifications
Individual-driven follow-up and escalation	Configured reminders and escalation thresholds
Periodic, fragmented visibility	Near real-time pending-incident and KPI view
Manual reporting effort	Dashboard-based operational and executive reporting
Baseline: 607 CMO-related incident dockets	Outcome: 494 CMO-related incident dockets (19% reduction)

6. Control Points

The automated workflow is controlled through input validation, duplicate suppression, owner-mapping validation, scheduled follow-up rules, approved escalation thresholds, audit logs and a documented manual fallback process. The system assists operational teams; it does not resolve network faults or replace authorized human decision-making.
